## Robust Weiszfeld's Structural Equation Modelling in Covariance Matrices

Hafeez Ahmed, Maznah Mat Kasim, Malina Zulkifli School of Quantitative Science, Universiti Utara Malaysia

### Abstract

The existing procedures for structural equation modelling involve in goodness of fit test for the sample covariance matrix by the structural model can no longer work in high dimensional datasets. The sample covariance can easily be influenced by outlier's presence in the datasets. This affect the estimation of the sample mean and sample covariance not being accurate and as well cause inefficiency in the computation. Therefore, there is need to suggest a robust covariance estimator the  $L_1$ -median with Weiszfeld algorithm that will resolve the outliers problem in high dimensional dataset. This test is subjected to conditions of sample size (n), variables (p) percentages of outliers  $(\varepsilon)$  with  $\alpha = 0.05$ . Simulation study carried out and the results show that when variable is minor both test performed but the new robust covariance test is better. At both middle and greater variables the existing test cannot compute the rate when p > n cases. Generally, the results shows that the newly incorporated robust covariance test performed better compare to the existing test.

### Introduction

The original methods for structural equation model include fitting the regular sample covariance matrix by a suggested maximum likelihood structural model. Since the assumption of normality required in the original estimation methods is frequently not satisfied in high dimensional datasets, Huber (1964). When number of observation, (p) is larger than the sample size, (n). The sample covariance matrix is easily influenced by a few outliers present, the usual exercise of modeling the sample covariance matrix can lead to inaccurate estimates as well as overestimated fit in high dimensional cases. Hence, causing the inability of the model to provide adequate fit or statistical explanation. However, when outliers exist in the data, the use of sample mean vector will result in poor estimation.

Thus, we need estimators which are robust to the existence of outliers to resolve the problem. In this research, in order to overcome these problem, several literatures are presented in statistics that highlight the importance of robustness of the sample covariance matrices. A wide range of robust estimators of multivariate location and scatter are available.

Some of them are based on the minimization of a robust scale of Mahalanobis distance such as Mestimator (Campbell, 1980), minimum volume ellipsoid (MVE), minimum covariance determinant (MCD) estimates {Rousseeuw & Driessen, 1999, Pison, Van Aelst & Willems, 2003), S-estimates (Davies, 1987), and  $\tau$ -estimates (Bianco & Boente, 2002). Others are based on projections, for example, the Stahel-Donoho estimate (SDE), *P*-estimates (Maronna, Stahel, & Yohai, 1992) and Kurtosis1 (Pena & Prieto, 2001). But, the minimum volume ellipsoid (MVE) and minimum covariance determinant (MCD) estimator introduced by Rousseeuw (1984; 1985) has received a considerable attention by scientific community and widely used in practice.

For high dimensional data computing, the MVE takes too much time and find it challenging to resolve the outlier's problem. Therefore, we proposed a modification of ML-test by incorporating the Weiszfeld's algorithm covariance matrix (Vardi & Zhang, 2000 Cardot & Godichon-Baggioni, 2017), for developing a new robust covariance matrix in the presence of outliers. To resolve the outlier's problem in high dimensional data sets. The most useful model in data analysis and outliers in high dimension is possibly the modelling of data by high dimensional data set with the median Weiszfeld's algorithm covariance matrix they are provably immune to outliers. Given data with a large fraction of extreme outliers, a robust estimator guarantees the returned value is still within the non-outlier part of the data (Tang & Phillips, 2016 and Arrigoni, Rossi, Fragneto & Fusiello, 2018).

## Methodology

Mathematically, the original ML-test is given as:

$$F_{ML}(\hat{\theta}) = \log |\mathbf{\Sigma}(\hat{\theta})| + tr\left(S\theta^{-1}(\hat{\theta})\right) - \log |S| - (p+q)$$

where  $\Sigma(\hat{\theta})$  is the variance structure,  $\hat{\theta}$  estimated parameters, tr is the trace of a matrix, S sample variance matrix,  $\theta^{-1}$  inverse of a matrix, p endogenous latent factors observation, and q the exogenous latent factors observation (Bollen, Kirby, Curran, Paxton & Chen, 2007).

The sample covariance matrix is most often assumed as the estimate of the population covariance matrix is most often assumed for this purposes is as:

$$S = 1/n \sum_{i=1}^{n} (\mathbf{x}^{(i)} - \bar{\mathbf{x}}) (\mathbf{x}^{(i)} - \bar{\mathbf{x}})',$$
(2)

where  $\overline{x} = \sum x^{(i)} / n \,$  is the mean of the sample covariance matrix.

In order to develop robust ML-test with SEM denoted by  $ML_{SEM}$ , the covariance of  $L_1$ -Weiszfeld,  $S_{L_1-Weiszfeld}$  where i = 1, 2, ..., m is replaced into Equation 1.

Therefore, the test now become the following,

 $F_{ML}(\hat{\theta}) = log|\mathbf{\Sigma}(\hat{\theta})| + tr\left(S_{L_1 - \text{Weiszfeld}}\theta^{-1}(\hat{\theta})\right) - log|S_{L_1 - \text{Weiszfeld}(i)}| - (p+q) \quad (3) \text{Where}$  $S_{L_1 - \text{Weiszfeld}} = 1/N \sum_{i=1}^m S_{L_1 - \text{Weiszfeld}(i)} \text{ is the pooled sample covariance matrix of } L_1 - \text{Weiszfeld} \text{ estimator.}$ 

 $L_1$  – Weiszfeld(*i*) is the number of subgroup where the stability of matrices is hypothesized.  $N = n_1 + n_2 + \dots + n_{L_1-\text{Weiszfeld}}$ ;  $n_i = i$ -th sample size. The measure of estimation that is performed in ML-test is the Type I error test rate on equation 1 and 3. The original test now become SEM<sub>0</sub>-test and modified SEM<sub>Weiszfeld</sub>-test, we be compared in terms performance.

(1)

### **Results and Discussions**

The main result is on robust covariance goodness of fit test in the presence of outliers. We compare original  $ML_{SEM}$ -test and modified  $ML_{SEM_{Weiszfeld}}$ - test in terms of Type I error rate. For each of the test 3 types of data contaminations are used to examine the strength and weakness of the tests. Also, all these tests have been open to various conditions which are number of variables (p), sample size (n), percentage of outliers  $(\varepsilon)$  and Mean Shift  $(\mu)$ . The summary of test comparison are in form of table. Start with sample size (n), in the first column in each of the table, followed by percentage of outliers  $(\varepsilon)$  and Mean Shift  $(\mu)$ . The following two columns detailed the Type I error rate of  $ML_{SEM}$ -test and the modified  $ML_{SEM_{Weiszfeld}}$ - test examined at different sample sizes in the study. The values that is closest to the significance level and within [0.025-0.075] are shaded in the tables with green and pink colours, whereas red colours denotes results cannot be computed.

In addition, Table 3.1 to 3.6 recorded the Type I error rate for each condition are arranged based on the ascending number of variables, specifically, minor, middle and greater variables (p = 15 and 18, p = 20 and 25, p = 30 and 50, respectively, n = 10, 20, 30, 40, 50, 60 and 70 with  $\alpha = 0.05$ .

## Type I Error for Minor Number of Variables (p = 15 and 18)

In Table 3.1 the Type I error rate of  $ML_{SEM}$  and  $ML_{SEM_{Weiszfeld}}$ -tests are recorded. The overall results show that  $ML_{SEM_{Weiszfeld}}$ -test is more robust compared to  $ML_{SEM}$ -test. All the values of Type I error rate of  $ML_{SEM}$ -test fall within the interval [0.025, 0.075] in blue when p = 15 and n = 10, 20, 30, 40, 60 and 70, except for conditions when  $\varepsilon = 0$  and  $\mu = 0$ , n = 40 and 70, at  $\varepsilon = 10$  and  $\mu = 3$  when n = 30, 40 and 70, at  $\varepsilon = 10$  and  $\mu = 5$  when n = 30, 40 and 70, at  $\varepsilon = 20$  and  $\mu = 5$  when n = 30, 40 and 70, at  $\varepsilon = 20$  and  $\mu = 5$  when n = 30, 40 and 70. Similarly, for  $ML_{SEM_{Weiszfeld}}$ -test shaded in green, when  $\varepsilon = 0$  and 10 and  $\mu = 0, 3$  and 5 only when n = 60 and 70, also, when  $\varepsilon = 20$  and  $\mu = 3$  and 5 only when n = 40, 60 and 70. From the results, it shows that  $ML_{SEM}$ -test is still well perform where 16 out of 30 conditions are non-robust, but  $ML_{SEM_{Weiszfeld}}$ -test is more robust compare to  $ML_{SEM}$ -test and performed very well 24 out of 30 fall within the robust interval.

In Table 3.2. The rate contamination cannot be computed when p > n cases. All the values of Type I error rate of  $ML_{SEM}$ -test fall within the interval [0.025, 0.075] in blue when p = 18 and n = 10, 20, 30, 40, 60 and 70, except for conditions when  $\varepsilon = 0$  and  $\mu = 0$ , n = 40 and 70, at  $\varepsilon = 10$  and  $\mu = 3$  when n = 40, 60 and 70, at  $\varepsilon = 10$  and  $\mu = 5$  when n = 30, 40 and 60, at  $\varepsilon = 20$  and  $\mu = 3$  when n = 30, 40, 60 and 70 and  $\varepsilon = 20$  and  $\mu = 5$  when n = 20, 30, 40, 60 and 70. Equally, for  $ML_{SEM_{Weiszfeld}}$ -test shaded in green, when  $\varepsilon = 0$  and 10 and  $\mu = 0, 3$  and 5 only when n = 40 and 70, also, when  $\varepsilon = 20$  and  $\mu = 3$  and 5 only when n = 60. From the results, it shows that  $ML_{SEM}$ -test is does not performed well, where 22 out of 30 conditions are non-robust. Besides,  $ML_{SEM_{Weiszfeld}}$ -test is more robust compare to  $ML_{SEM}$ -test and performed very well 23 out of 30 fall within the robust interval.

|          |              |                 |                   |                            |

Table 3.2: Type I error rates for the corresponding p = 18

## Type I Error for Middle Number of Variables (p = 20 and 25)

In Table 3.3 the Type I error rate of ML<sub>SEM</sub> and ML<sub>SEMweiszfeld</sub>-tests are recorded. The overall results show that  $ML_{SEM_{Weiszfeld}}$ -test is more robust compared to  $ML_{SEM}$ -test. The rate contamination cannot be computed when p>n cases. All the values of Type I error rate of  $ML_{SEM}$ -test fall within the interval [0.025, 0.075] in blue when p = 20 and n = 10, 20, 30, 40, 60 and 70, except for conditions when  $\varepsilon = 0$  and  $\mu = 0$ , n = 40 and 60, at  $\varepsilon = 10$  and  $\mu = 3$  when n = 30, 60 and 70, at  $\varepsilon = 10$  and  $\mu = 5$  when n = 30, 40 and 70, at  $\varepsilon = 20$  and  $\mu = 3$  when n = 40, 60 and 70 and  $\varepsilon = 10$ 20 and  $\mu = 5$  when n = 30, 40, 60 and 70. Likewise, for  $ML_{SEM_{Weiszfeld}}$ -test shaded in green, when  $\varepsilon = 0$  and 10 and  $\mu = 0, 3$  and 5 only when n = 40 and 70, also, when  $\varepsilon = 20$  and  $\mu = 3$  and 5 only when n = 40 and 70. From the results, it shows that  $ML_{SEM}$ -test is not well perform where 23 out of 30 conditions are non-robust. Also,  $ML_{SEM_{Weiszfeld}}$ -test is more robust compare to  $ML_{SEM}$ -test and performed very well 22 out of 30 fall within the robust interval. In Table 3.4. The Type I error rate of  $ML_{SEM}$ -test fall within the interval in blue when p = 25, except for conditions when  $\varepsilon = 0$  and  $\mu = 0$ , n = 60 and 70, at  $\varepsilon = 10$  and  $\mu = 3$  and 5 when n = 40, 60 and 70, at  $\varepsilon = 20$  and  $\mu = 10$ 3 and 5, none of the *n*. Also, for  $ML_{SEM_{Weiszfeld}}$ -test shaded in green colours, when  $\varepsilon = 0$  and 10 and  $\mu = 0,3$  and 5 only when n = 30,40 and 70, also, when  $\varepsilon = 20$  and  $\mu = 3$  and 5 only when n = 10,340 and 70. From the results, it shows that ML<sub>SEM</sub>-test is not well performed where 4 out of 30 conditions are non-robust. Also,  $ML_{SEM_{Weiszfeld}}$ -test is more robust compare to  $ML_{SEM}$ -test and perform very well 24 out of 30 fall within the robust interval.

|          |           |      |       | 4                 | 24                         |  |

Table 3.4: Type I error rates for the corresponding p = 25

Shaded region indicate Type I error within [0.025-0.075]

## Type I Error for Greater Number of Variables (p = 30 and 50)

In Table 3.5 the Type I error rate of  $ML_{SEM}$  and  $ML_{SEM_{Weiszfeld}}$ -tests are recorded. The overall results show that  $ML_{SEM_{Weiszfeld}}$ -test is more robust compared to  $ML_{SEM}$ -test. The rate contamination cannot be computed when p > n cases. All the values of Type I error rate of  $ML_{SEM}$ -test fall within the interval [0.025, 0.075] in blue when p = 30 and n = 10, 20, 30, 40, 60 and 70, except for conditions when  $\varepsilon = 0$  and  $\mu = 0$ , n = 40 and 60, at  $\varepsilon = 10$  and  $\mu = 3$  when n = 40, 60 and 70, at  $\varepsilon = 10$  and  $\mu = 5$  when n = 40, 60 and 70, at  $\varepsilon = 20$  and  $\mu = 5$  when n = 40, 60 and 70. Likewise, for  $ML_{SEM_{Weiszfeld}}$ -test shaded in green, when  $\varepsilon = 0$  and  $\mu = 0$ , when n = 40 and 70, also, when  $\varepsilon = 10$  and  $\mu = 3$  and 5 only when n = 30, 40 and 70, when  $\varepsilon = 20$  and  $\mu = 3$  and 5, when n = 30, 40 and 70. From the results, it shows that  $ML_{SEM}$ -test is more robust compare to  $ML_{SEM}$ -test and performed very well 19 out of 30 fall within the robust interval.

In Table 3.6. The Type I error rate of  $ML_{SEM}$ -test fall within the interval in blue colour when p = 50, all the conditions are not robust. Similarly, for  $ML_{SEM_{Weiszfeld}}$ -test shaded in green, when  $\varepsilon = 0$  and  $\mu = 0$ , when n = 30, 40 and 70, also, when  $\varepsilon = 10$  and  $\mu = 3$  and 5 only when n = 40 and 70, when  $\varepsilon = 20$  and  $\mu = 3$  and 5 only when n = 30, 40 and 70, also, when  $\varepsilon = 10$  and  $\mu = 3$  and 5 only when n = 40 and 70, when  $\varepsilon = 20$  and  $\mu = 3$  and 5 only when n = 30, 40 and 70. From the results, it shows that  $ML_{SEM}$ -test performed worst 30 out of 30 conditions are non-robust. Also,  $ML_{SEM_{Weiszfeld}}$ -test is more robust compare to  $ML_{SEM}$ -test and performed very well 19 out of 30 fall within the robust interval.

| Sample       | Size | % Outlier (ɛ) | Mean | Shift |                   | Robust Tests                             |

Table 3.6: Type I error rates for the corresponding p = 50

Shaded region indicate Type I error within [0.025-0.075]

In conclusion, there are 60 conditions involved in evaluating the robustness of test for minor number of variables (p = 15 and 18). There are 22 out 60 conditions of ML<sub>SEM</sub>-test, and 47 condition of ML<sub>SEMWeiszfeld</sub>-test fall within the robust interval. When, p = 15, there are 14 out 30 and p = 18, also 8 out 30 of ML<sub>SEM</sub>-test, and 24 out of 30 and 23 out of 30 ML<sub>SEMWeiszfeld</sub>-test respectively that fall within the interval. Likewise, when (p = 20 and 25). There are 11 out 60 conditions of ML<sub>SEM</sub>-test, and 46 condition of ML<sub>SEMWeiszfeld</sub>-test and for, p = 20, there are 7 out 30 and p = 25, there are 4 out 30 of ML<sub>SEMWeiszfeld</sub>-test fall within the robust interval. When (p = 30 and p = 25, there are 1 out 60 conditions of ML<sub>SEMWeiszfeld</sub>-test fall within the robust interval. When (p = 30 and 50). There are 1 out 60 conditions of ML<sub>SEMWeiszfeld</sub>-test fall within the robust interval. When (p = 30 and 50). There are 1 out 60 conditions of ML<sub>SEM-test</sub>, and 38 condition of ML<sub>SEMWeiszfeld</sub>-test and for, p = 30, there are 1 out 60 conditions of ML<sub>SEM-test</sub>, and 38 condition of ML<sub>SEMWeiszfeld</sub>-test and for, p = 30, there are 1 out 30 and p = 50, none of ML<sub>SEM</sub>-test, and , p = 30, there are 19 out 30 and p = 50, there are 19 out 30 of ML<sub>SEMWeiszfeld</sub>-test fall within the robust interval.

In general we derive the new statistical robust estimator using the Weiszfeld's algorithm covariance matrix to resolve the outliers' problem in high dimensional data sets. The robust estimator can computed the results based on when p > n with  $ML_{SEM_{Weiszfeld}}$ -test in structural equation modelling.
